orchardgrass and alfalfa forages were ensiled by various treatments of air exclusion or inclusion to provide silages of different qualities the forages were prepared in this manner to study the bacteriological and chemical processes in good and poor silages it was felt that a knowledge of the underlying mechanism involved in forages of this type would aid in establishing better silage making techniques the results of this study showed that different quality silages could be obtained by varying the amount of air excluded or included in forages the good quality silages were characterized by ph values of 4 8 or below low ammoniacal nitrogen and considerable amounts of lactic acid some of these silages contained traces of butyric acid and low spore counts but usually none were found a reversal of these values was noted for the poor quality silages the intermediate quality silages showed values similar to both the good and poor quality silages
